Song recommender

Introduction

- **Goals**
 - Expand and improve music recommendation for the user
 - Recommend songs (not only bands)
 - Increase website traffic in order to promote company growth
- **Desired outcome**
 - The user inputs a song from one “group” and the output is recommendations of songs from that same “group”
- **Outcome workflow**
 - With the users input, the program will analyse it and predict:
 - Songs that are actually similar to the ones they picked from an acoustic point of view
 - Songs that are popular around the world right now, independently from their tastes

Process

Collect the current popular songs

Create clusters based on the songs audio features

Collect a mix of songs with different features (genre, audio, etc) not considered popular at the moment

Add the user input song to the cluster it belongs and recommend a similar song

Outcome

- As current hot songs
 - The Billboard top 100
- As not so hot songs:
 - A website with the 3000 most popular songs of all time
- Spotify API to collect the songs information and audio features
- Clustering based on the audio features in order to recommend a similar song
